

SUMMARY OF PRODUCT CHARACTERISTICS

1 NAME OF THE MEDICINAL PRODUCT

Prednisolone 4 mg Tablets

2 QUALITATIVE AND QUANTITATIVE COMPOSITION

Each tablet contains Prednisolone 4 mg

Excipients with known effect

Also contains lactose (59.46 mg).

For the full list of excipients, see section 6.1

3 PHARMACEUTICAL FORM

Tablet

White or creamy white, biconvex, plain tablets. "P4" engraved on one side and plain on the other side, with a diameter of approximately 5.5mm.

4.1 Therapeutic indications

Allergy and anaphylaxis:

Bronchial asthma, drug hypersensitivity reactions, serum sickness, angioneurotic oedema, anaphylaxis, incapacitating allergies unresponsive to conventional treatment.

Arteritis/collagenosis:

Giant cell arteritis/polymyalgia rheumatica, mixed connective tissue disease, polyarteritis nodosa, polymyositis

Blood disorders:

Haemolytic anaemia (auto-immune), leukaemia (acute and chronic lymphocytic), lymphoma, multiple myeloma, idiopathic thrombocytopenic purpura

Cardiovascular disorders:

Post-myocardial infarction syndrome, rheumatic fever with severe carditis

Endocrine disorders:

Primary and secondary adrenal insufficiency, congenital adrenal hyperplasia

Gastro-intestinal disorders:

regional ileitis (Crohn's disease), ulcerative colitis, persistent coeliac syndrome (celiac disease unresponsive to gluten withdrawal), auto-immune chronic active hepatitis, multisystem disease affecting liver, biliary peritonitis

Hypercalcaemia:

Sarcoidosis, vitamin D excess

Infections (with appropriate chemotherapy):

Helminthic infestations, Herxheimer reaction, infectious mononucleosis, miliary tuberculosis, mumps orchitis (adult), tuberculous meningitis, rickettsial disease

Muscular disorders:

Polymyositis, dermatomyositis

Neurological disorders:

Infantile spasms, Shy-Drager syndrome, sub-acute demyelinating polyneuropathy

Ocular disease:

Scleritis, posterior uveitis, retinal vasculitis, pseudo-tumours of the orbit, giant cell arteritis, malignant ophthalmic Graves disease

Renal disorders:

Lupus nephritis, acute interstitial nephritis, minimal change glomerulonephritis, nephrotic syndrome

Respiratory disease:

Allergic pneumonitis, asthma, occupational asthma, pulmonary aspergillosis, pulmonary fibrosis, pulmonary alveolitis, aspiration of foreign body, aspiration of stomach contents, pulmonary sarcoid, drug-induced lung disease, adult respiratory distress syndrome, spasmodic croup, fulminating or disseminated pulmonary tuberculosis when used concurrently with appropriate antituberculosis chemotherapy.

Rheumatic disorders:

Rheumatoid arthritis, polymyalgia rheumatica, juvenile chronic arthritis, systemic lupus erythematosus, dermatomyositis, mixed connective tissue disease and psoriatic arthritis,

Skin disorders:

Pemphigus vulgaris, exfoliative dermatitis, bullous pemphigoid, systemic lupus erythematosus, pyoderma gangrenosum

Miscellaneous:

Sarcoidosis, hyperpyrexia, Behçets disease, immunosuppression in organ transplantation,

4.2 Posology and method of administration

Posology

Adults and the elderly

The lowest effective dose should be used for the minimum period.

Children

Prednisolone should only be used when specifically indicated, at the lowest dose possible and for the shortest possible time.

The initial dosage of prednisolone may vary from 5 mg to 60 mg daily depending on the disorder being treated. Divided daily dosage is usually used. Administration as a once daily dose in the morning or on alternate days can reduce the risk of adrenocortical suppression (see Section 4.4 Special warnings and precautions for use). In some patients this may not be possible e.g. patients with rheumatoid arthritis with pronounced morning stiffness where an evening dose may need to be given.

The following therapeutic guidelines should be kept in mind for all therapy with corticosteroids:

The lowest dose to produce an acceptable result should be given. Initial dosage should be adjusted until the desired clinical response has been achieved. The dose should be gradually reduced until the lowest dose which will maintain an adequate clinical response is reached. As a guide, the daily dose should be reduced by 2.5 – 5 mg every second to fifth day (more rapidly at the higher initial dose levels) until the lowest possible maintenance dose is reached. Preferably this should not exceed 10 mg per day. Use of the lowest effective dose may also minimise side-effects. The incidence of side-effects increases with dose and duration of treatment (see section 4.4).

Particular care should be exercised in patients who have received higher than 7.5mg prednisolone daily or equivalent for more than 3 weeks, owing to a greater risk of suppression of the hypothalamic-pituitary-adrenal (HPA) axis in these patients. The speed with which dose can be reduced is also dependent on risk of relapse of the disease being treated. After prolonged treatment, tapering of dose below 7.5 mg (regarded as “equivalent” to physiological levels of glucocorticoids) should be conducted particularly cautiously..

More rapid withdrawal of systemic corticosteroid treatment that has been given for less than 3 weeks is appropriate if it is considered that the disease

is unlikely to relapse. Withdrawal of doses of up to 40mg daily of prednisolone, or equivalent have been administered for less than 3 weeks is unlikely to lead to clinically relevant HPA-axis suppression, in the majority of patients. In the following patient groups, gradual withdrawal of systemic corticosteroid therapy should be considered even after courses lasting 3 weeks or less.

- patients who have had repeated courses of systemic corticosteroids, particularly if taken for greater than 3 weeks.
- when a short course has been prescribed within one year of cessation of long-term therapy (months or years).
- patients who may have reasons for adrenocortical insufficiency other than exogenous corticosteroid therapy.
- patients receiving doses of systemic corticosteroid greater than 40mg daily of prednisolone (or equivalent).
- patients repeatedly taking doses in the evening.

(See Section 4.4 'Special warnings and special precautions for use' and Section 4.8 'Undesirable effects')

During prolonged therapy, dosage may need to be temporarily increased during periods of stress or during exacerbations of the disease (see Section 4.4 'Special warnings and special precautions for use')

If there is lack of a satisfactory clinical response to Prednisolone Tablets, the drug should be gradually discontinued and the patient transferred to alternative therapy.

Intermittent dosage regimen

A single dose of prednisolone tablets in the morning on alternate days or at longer intervals is acceptable therapy for some patients. When this regimen is practical, the degree of pituitary- adrenal suppression can be minimised.

Specific dosage guidelines

The following recommendations for some corticosteroid- responsive disorders are for guidance only. Acute or severe disease may require initial high dose therapy with reduction to the lowest effective maintenance dose as soon as possible. Dosage reductions should not exceed 5-7.5 mg daily during chronic treatment.

Allergic and skin disorders

Initial doses of 5-15 mg daily are commonly adequate.

Collagenosis

Initial doses of 20-30 mg daily are frequently effective. Those with more severe symptoms may require higher doses.

Rheumatoid arthritis

The usual initial dose is 10-15 mg daily. The lowest daily maintenance dose compatible with tolerable symptomatic relief is recommended.

Blood disorders and lymphoma

An initial daily dose of 15-60 mg is often necessary with reduction after an adequate clinical or haematological response. Higher doses may be necessary to induce remission in acute leukaemia.

Specific populations

Use in Elderly:

Treatment of elderly patients, particularly if long-term, should be undertaken with caution bearing in mind the more serious consequences of the common side-effects of corticosteroids in old age (see also section 4.4).

Use in Children:

Although appropriate fractions of the adult dosage may be used be determined by clinical response as in adults (see also section 4.4 and 4.8). Alternate day dosage is preferable where possible.

Method of administration

Prednisolone tablets should be taken following a meal to reduce the risk of gastric irritation.

4.3 Contraindications

1. Hypersensitivity to Prednisolone or to any of the excipients listed in section 6.1.
2. Systemic yeast infection
3. Administration of live vaccines is contraindicated in patients receiving corticosteroids immunosuppressive doses.
4. In those conditions when treatment with prednisolone can save lives, none of the contraindications generally apply. .

4.4 Special warnings and precautions for use

Since the complications of glucocorticoid therapy are dependent on the dose and duration of treatment, a risk / benefit assessment must be made in each case regarding dose and duration of treatment, as well as whether daily or intermittent treatment should be used.

The lowest possible corticosteroid dose needed to control the disease being treated should be used. When dose reduction is possible, it should be gradual.

Immunosuppressive effects/ increased susceptibility to infection:

Glucocorticoids, including prednisolone, may cause increased susceptibility to infection, masking symptoms of infection, and new infections may occur during treatment.

Infections caused by viruses, bacteria, fungi, protozoa or intestinal worms may be associated with the use of corticosteroids alone or corticosteroids in combination with other immunosuppressive agents that affect cellular immunity, humoral immunity or the function of neutrophils. The infections can be mild, but also difficult and in some cases fatal. The risk of infectious complications increases with increasing dose.

Glucocorticoids should not be given during infections without concomitant causal treatment.

Chickenpox and measles can be more serious or even fatal in non-immunised children and adults treated with corticosteroids. Children, or adults who have not had these diseases, and who take immunosuppressive doses of corticosteroids, should be advised to avoid exposure to chickenpox and measles, and to seek care when exposed.

The use of prednisolone in active tuberculosis must be limited to those cases of fulminant or disseminated tuberculosis where the corticosteroid is used to treat the disease in combination with appropriate tuberculosis therapy. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close monitoring is necessary as the disease can be reactivated. In long-term corticosteroid therapy, these patients should receive tuberculosis prophylaxis.

High dose corticosteroids may interfere with active immunisation.

Vaccination with live vaccine should be done under close supervision and not in patients on long-term treatment with corticosteroids in immunosuppressive doses.

Immune system

Since rare cases of skin reactions and anaphylactic / anaphylactoid reactions have occurred in patients treated with corticosteroids, appropriate precautions should be taken prior to administration, especially if the patient has previously had an allergic reaction to any drug.

Endocrine system

Long-term treatment with pharmacological doses of corticosteroid may lead to secondary adrenal insufficiency. The risk can be reduced by giving the treatment every other day (see section 4.2).

Patients who receive corticosteroid maintenance therapy and are exposed to unusual stresses (e.g. infection, surgery or trauma) need higher corticosteroid doses before, during and after the stressful situation.

Abrupt discontinuation of treatment may lead to acute adrenal insufficiency which may be fatal. The risk of secondary adrenal insufficiency can be reduced by gradually decreasing the dose. This type of relative insufficiency may persist for months after the end of treatment, ; so hormone replacement therapy should be reintroduced in stressful situation occurring during that period. Since mineralocorticoid secretion may be impaired, salt and/or a mineralocorticoid should be administered concurrently.

A "steroid withdrawal syndrome", apparently without associated adrenal insufficiency, may also occur following abrupt withdrawal of glucocorticoids. This syndrome causes symptoms such as anorexia, nausea, vomiting, lethargy, headache, fever, joint pain, desquamation, myalgia, weight loss and / or hypotension. These effects are believed to be due to the sudden change in glucocorticosteroid concentration rather than to low corticosteroid levels

There is an enhanced effect of corticosteroids in patients with hypothyroidism or liver cirrhosis..

Pheochromocytoma-related crisis, which may be fatal, has been reported following systemic corticosteroid administration. Corticosteroids should only be administered to patients with suspected or identified pheochromocytoma following consideration of individual risk / benefit.

Metabolism and nutrition

Corticosteroids, including prednisolone, can raise blood sugar levels, worsen existing diabetes and increase the risk of developing diabetes in patients on long-term corticosteroid therapy.

Mental disorders

Potentially serious mental disorders may occur during treatment with corticosteroids including prednisolone. It can be anything from euphoria, sleep disorders, mood swings, personality changes, and severe depression, to frank psychotic manifestations.

Existing emotional instability and psychotic tendencies can also be exacerbated by corticosteroids(see Section 4.8 'Undesirable effects'). The symptoms typically begin within a few days or weeks after the start of treatment. Most reactions return after dose reduction or withdrawal, but specific treatment may be necessary.

Psychiatric effects have been reported with the withdrawal of corticosteroids, the frequency is unknown. Patients / caregivers should be encouraged to seek medical care if the patient shows mental symptoms, especially if depression or suicidal thoughts are suspected. Patients / caregivers should be aware that

mental disorders may occur either during or immediately after dose reduction / discontinuation of systemic steroids.

Central and peripheral nervous system

Corticosteroids should be used with caution in patients with seizures.

Heart

Side effects of glucocorticoids on the cardiovascular system, for example dyslipidaemia and hypertension, can predispose in treated patients with existing cardiovascular risk factors for additional cardiovascular events at high doses and prolonged treatment times. Corticosteroids should therefore be introduced to these patients only after careful consideration, and risk-modifying measures as well as extra cardiac monitoring should be considered as needed. Low dose and treatment every other day can reduce the complications of corticosteroid treatment.

Blood vessels

Since cortisone has been reported to increase the blood clotting tendency in rare cases, thereby accelerating the development of intravascular thrombosis, thromboembolism and thrombophlebitis, corticosteroids should be used with caution in patients with thromboembolic disorders.

Gastrointestinal tract

High doses of corticosteroids can cause acute pancreatitis.

There are no conclusive data that states that corticosteroids cause ulcers.

Glucocorticoid therapy can mask peritonitis and other signs and symptoms associated with gastrointestinal conditions such as perforation, obstruction or pancreatitis. In combination with NSAIDs, the risk of gastrointestinal ulcers is increased.

Corticosteroids should therefore be used with caution in non-specific ulcerative colitis if there is a likelihood of imminent perforation, abscess or other pyogenic infection, diverticulitis, newly created anastomoses, or active or latent peptic ulcer.

Liver and biliary tract

Diseases of the liver and bile ducts have been reported rarely and in the majority of these cases the condition was reversible after discontinuation of treatment. Appropriate monitoring measures are required.

Musculoskeletal system

Acute myopathy has been reported with high corticosteroid doses, most often in patients with neuromuscular transmission disorders (e.g., myasthenia gravis), or in patients concomitantly treated with anticholinergics, e.g. neuromuscular blocking drugs (such as pancuronium) (see section 4.5). This acute myopathy is generalised, may involve eye and respiratory muscles, and may lead to tetraparesis. Elevated creatine kinase may occur. Clinical improvement or recovery after discontinuation of corticosteroid therapy may take weeks or years.

Corticosteroids should be used with caution in patients with osteoporosis

Kidneys and urinary tract

Corticosteroids should be used with caution in patients with renal insufficiency.

Scleroderma renal crisis

Caution is required in patients with systemic sclerosis because of an increased incidence of (possibly fatal) scleroderma renal crisis with hypertension and decreased urinary output observed with a daily dose of 15 mg or more prednisolone. Blood pressure and renal function (s-creatinine) should therefore be routinely checked. When renal crisis is suspected, blood pressure should be carefully controlled.

Effects on electrolytes and fluid balance

Systemic corticosteroids should be used with caution in patients with heart failure or hypertension. Medium and high doses of hydrocortisone or cortisone can lead to increased blood pressure, salt and water retention and increased potassium secretion. These effects are less likely with synthetic derivatives, except when used in high doses. Dietary restrictions with lower salt intake and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

Visual disturbances

Visual disturbances may be reported with systemic and topical corticosteroids use. If a patient present with symptoms such as blurred vision or other visual disturbances, patient should be considered for referral to an ophthalmologist for evaluation of possible causes, which may include cataract, glaucoma or rare diseases such as central serous chorioretinopathy (CSCR), which have been reported after use of systemic and topical corticosteroids.

Tumour lysis syndrome (TLS)

Tumour lysis syndrome (TLS) has been reported post-marketing in patients with malignancies, including haematological malignancies and solid tumours, following the use of systemic corticosteroids alone or in combination with other cytotoxic agents. Patients at high risk for TLS, such as patients with tumours that have a high rate of cell division, high tumour burden, and high sensitivity to cytotoxic agents, should be closely monitored and appropriate precautions taken.

Paediatric population

Corticosteroids cause growth inhibition in infants, children and adolescence, therefore long-term administration of pharmacological doses. If long-term treatment is required, the infant / child's growth and development should be closely monitored (see section 4.2). Infants and children who are on long-term corticosteroid therapy are at particular risk of developing elevated intracranial pressure.

Excipients

Patients with rare hereditary problems of galactose intolerance, total lactase deficiency or glucose-galactose malabsorption should not take this medicine.

This medicine contains less than 1 mmol sodium (23 mg) per tablet, that is to say essentially 'sodium-free'

4.5 Interaction with other medicinal products and other forms of interaction

The following combinations with Prednisolone may require dose adjustment.

Carbamazepine, phenobarbital, phenytoin:

Phenobarbital (which is also the metabolite of primidone), phenytoin and carbamazepine alone and in combination, induces the metabolism of hydrocortisone, prednisolone and methylprednisolone (shown in children with asthma) with increased dose requirements as a result. The interaction probably applies to the whole group of glucocorticoids..

Non-steroidal anti-inflammatory drugs:

- 1) The incidence of gastrointestinal bleeding and ulceration may increase if corticosteroids are given with NSAIDs.
- 2) Corticosteroids may increase the clearance of high doses of acetylsalicylic acid, which may lead to lower salicylate levels in the serum. Salicylate levels in serum may increase upon discontinuation of corticosteroid therapy, which could lead to an increased risk of toxic effects of salicylate.

Antidiabetic agents:

Glucocorticoids may increase blood glucose levels. Patients with diabetes mellitus receiving concurrent insulin and/or oral hypoglycemic agents may require dosage adjustments of such therapy.

Oestrogens (also oral contraceptives containing oestrogens):

Oestrogens increase the concentration of transcortin. The effect of glucocorticoids that bind to transcortin can be enhanced and dose adjustments may be needed if oestrogens are added or removed from a stable treatment regimen..

Potassium Reducing Agents:

Potassium-reducing diuretics (e.g., thiazides, furosemide, ethacrynic acid) and other drugs that reduce the amount of potassium such as amphotericin B, xanthines and beta2-agonists, may potentiate the potassium-lowering effect of glucocorticoids. Serum potassium should be closely monitored in patients receiving glucocorticoids and potassium reducing agents.

Rifampicin:

Rifampicin induces the microsomal oxidation of glucocorticoids (hydrocortisone, prednisolone, methylprednisolone). This leads to an

increased steroid need during rifampicin treatment and reduced steroid need after such treatment.

Isoniazid:

Prednisolone also has a potential effect which results in increased acetylation rate and clearance of isoniazid.

Anticoagulants:

There are reports of altered effects of anticoagulants given concurrently with prednisolone. Prothrombin time (INR) should be monitored during treatment.

CYP3A inhibitors, including medicinal products containing cobicistat:

Co-treatment with CYP3A inhibitors, including cobicistat-containing products, is expected to increase the risk of systemic side-effects. The combination should be avoided unless the benefit outweighs the increased risk of systemic corticosteroid side-effects, in which case patients should be monitored for systemic corticosteroid effects.

Anticholinergic, neuromuscular blockers:

Corticosteroids may affect the effect of anticholinergics.

- 1) Acute myopathy has been reported with concomitant use of high doses of corticosteroids and anticholinergics such as neuromuscular blockers (see section 4.4).
- 2) Antagonism with the neuromuscular blocking effect of pancuronium and vecuronium has been reported in patients taking glucocorticosteroids. This interaction can be expected with all competitive neuromuscular blockers.

Anticholinesterases:

Interaction between glucocorticoids and anticholinesterases such as ambenonium, neostigmine and pyridostigmine may lead to significant potency in myasthenia gravis.

If possible, treatment with anticholinesterase should be discontinued at least 24 hours before administration of glucocorticoid.

4.6 Fertility, Pregnancy and lactation

Fertility:

Animal studies have shown that corticosteroids impair fertility (see section 5.3).

Pregnancy:

In animal studies, corticosteroids have been shown to give rise to various types of malformations (palate gap, skeletal malformations, see section 5.3).

The relevance in humans is unknown.

After long-term treatment, reduced placental and birth weight have been observed in humans and animals.

In addition, there is a risk of adrenal cortex failure in the newborn during long-term treatment. Therefore, during pregnancy, corticosteroids should be given after special consideration.

Breast Feeding:

Prednisolone passes into breast milk, but the risk of affecting the baby seems unlikely with therapeutic doses.

4.7 Effects on ability to drive and use machines

The effect of corticosteroids on the ability to drive and use machines has not been systematically investigated.

Side effects such as dizziness, visual disturbances and fatigue are possible after treatment with corticosteroids. In such adverse reactions, patients should not drive or use machines.

4.8 Undesirable effects

Apart from substitution therapy, corticosteroid treatment always involves an overdose compared to the physiological state. Side effects mainly occur with long-term treatment, but also depend on dose size and individual sensitivity.

Undesirable effects are listed by MedDRA System Organ Classes. Assessment of undesirable effects is based on the following frequency groupings:

Very common: $\geq 1/10$

Common: $\geq 1/100$ to $< 1/10$

Uncommon: $\geq 1/1,000$ to $< 1/100$

Rare: $\geq 1/10,000$ to $< 1/1,000$

Very rare: $< 1/10,000$

Not known: cannot be estimated from the available data

System Organ Class	Frequency	Undesirable Effect
Infections and Infestations	Common	opportunistic infections, Activation of infection(e.g., tuberculosis)
Blood and lymphatic system disorders	Not known	leucocytosis (due to redistribution of intravascular granulocytes).
Immune system disorders	Not known	drug hypersensitivity, anaphylactic reaction, anaphylactoid reaction.
Endocrine disorders	Common	inhibition of the hypothalamicpituitary-adrenal (HPA) axis, cushing-like symptoms. growth retardation (in children)

	Not known	steroid withdrawal syndrome (see section 4.4), Pheochromocytoma – related crisis (see section 4.4)..
Metabolism and nutrition disorders	Common	hypokalaemia, sodium retention, increased gluconeogenesis, catabolic effects, osteoporosis
	Not known	metabolic acidosis, fluid retention, hypokalaemic alkalosis, reduced glucose intolerance (diabetes mellitus may deteriorate and latent diabetes become manifest) . lipomatosis, Increased appetite(Which weight gain) dyslipidaemia.
Psychiatric disorders	Uncommon	activation of previous mental disorders (high dose)
	Rare	depression, mania in patients without previously known mental illness
	Not known	affective disorder (includes euphoria, affective lability, drug-related, suicidal condition), psychotic disorder (includes delusions, hallucinations and schizophrenia) mental illness, , personality change, mood swings, abnormal behaviour, insomnia, irritability.
Nervous system disorders	Rare	Benign intracranial hypertension
	Not known	amnesia, Cognitive disorder, dizziness, headache, epidural lipomatosis. seizure
Eye disorders	Uncommon	cataract, glaucoma, vision blurred (see section 4.4)
	Not known	Central serous chorioretinopathy (see section 4.4) exophthalmos,
Cardiac disorders	Not known	congestive heart failure in susceptible patients, bradycardia **
Vascular disorders	Common	oedema hypertension
	Not known	thromboembolism events.
Respiratory, thoracic and mediastinal disorders	Not known	hiccup
Gastrointestinal disorders	Not known	dyspepsia, nausea, peptic wound (possibly with perforation and bleeding), abdominal distension, abdominal pain, diarrhoea, oesophageal ulceration, intestinal perforation pancreatitis.
Skin and	Common	skin atrophy, impaired wound healing

subcutaneous tissue disorders	Not known	angioedema, hirsutism, petechiae, ecchymosis, erythema hyperhidrosis, stretch marks, itching, acne, urticaria.
Musculoskeletal and connective tissue disorders	Common	muscular atrophy
	Rare	aseptic bone necrosis, tendon rupture
	Not known	muscle weakness, myalgia, neuropathic arthropathy, arthralgia, myopathy, pathological fracture
Renal and urinary disorders	Not known	scleroderma renal crisis*
Reproductive system and breast disorders	Not known	menstrual irregularity,
General disorders and administration site conditions	Not known	fatigue, malaise,
Investigations	Not known	Increased calcium levels in the urine, Elevated alanine aminotransferase, Elevated aspartate aminotransferase, Increased blood alkaline phosphatase, Elevated blood urea, suppression of skin tests reactions ¹ .

¹ Not MedDRA term

*Scleroderma renal crisis

Amongst the different subpopulations the occurrence of scleroderma renal crisis varies. The highest risk has been reported in patients with diffuse systemic sclerosis. The lowest risk has been reported in patients with limited systemic sclerosis (2%) and juvenile onset systemic sclerosis (1%)

** Following high doses

Reporting of suspected adverse reactions

Reporting suspected adverse reactions after authorisation of the medicinal product is important. It allows continued monitoring of the benefit/risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions via the Yellow Card Scheme, Website: www.mhra.gov.uk/yellowcard or search for MHRA Yellow Card in the Google Play or Apple App Store.

4.9 Overdose

Reports of acute toxicity and/or death following overdosage of glucocorticoids are rare.

Possibly, acute overdose may aggravate preexisting disease states such as ulcers, electrolyte disorders, infections and oedema.

Treatment: Not usually required. If proper gastric emptying, with charcoal. In case of overdose, there is no specific antidote, but the treatment is supportive and symptomatic.

5.1 **Pharmacodynamic properties**

Pharmacotherapeutic group: Corticosteroids for systemic use. ATC code: H02AB06.

Synthetic glucocorticoid with anti-inflammatory, immunosuppressive and antiallergic action.

Prednisolone has, by weight, 4-5 times higher anti-inflammatory effect than cortisone, but affects electrolyte turnover to a lesser extent.

The mechanism of action is not yet fully understood.

5.2 **Pharmacokinetic properties**

Absorption

Prednisolone is readily absorbed into the gastro-intestinal tract after oral administration. Maximum plasma concentrations is achieved after 1 to 2 hours after oral administration. The plasma half-life is normally 2 to 4 hours. Its initial absorption, but not its overall bioavailability, is affected by food.

Distribution

Prednisolone is highly bound to plasma proteins and has high affinity for the transcortin.

The volume of distribution and clearance are reported to increase with transition from low to medium doses.

Metabolism

Prednisolone is metabolised primarily in the liver to a biologically inactive compound.

Prednisolone can be reversibly converted to prednisone by 11β -hydroxysteroid dehydrogenase.

The absolute bioavailability of prednisolone is on average 82% compared to intravenously administered prednisolone following a single 10 mg dose. At normal dosing, the effective duration is calculated to be 12-36 hours.

Elimination

Prednisolone is excreted in the urine as free and conjugated metabolites, along with small amount of unchanged Prednisolone.

More than 90% of the given amount is excreted in the urine. 7-15% is excreted in unchanged form.

5.3 Preclinical safety data

In animal experiments, corticosteroids have been shown to give rise to various types of malformations (palate gap, skeletal malformations). After long-term treatment, reduced placental and birth weight have been observed in animals. Corticosteroids have been shown to reduce fertility when administered to the rat.

6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients

Lactose

Maize starch

Starch pregelatinised

Sodium starch glycollate (Type A)

Magnesium stearate

6.2 Incompatibilities

Not applicable

6.3 Shelf life

3 years

6.4 Special precautions for storage

Do not store above 25°C.

6.5 Nature and contents of container

White/Opaque 250 µm PVC and 25 µm aluminium foil coated with heat-seal lacquer on one side.

Blister packs of 28 tablets.

6.6 Special precautions for disposal

Not applicable
